

# Easy B Facts

## If 100 Infants Were Infected with HBV

- 100 Newborns → Initial Infection
- 10 Newborns → Recover After a Brief Infection
- 90 Newborns → Develop a Chronic Life-Term Infection
- 18 Newborns → Eventually Die from Liver Disease

### If 100 infants were infected with the hepatitis B virus (HBV):

- Only 10 of the 100 newborns born to mothers infected with HBV would develop a short-lived or acute infection. Their immune systems would be able to fight off and clear the infection within a few weeks.
- About 90 out of the 100 newborns would not be able to clear the virus from their bodies, and they would develop a serious, potentially life-long HBV infection (Chronic HBV). In most, many years and decades would pass before HBV infection made their livers very sick from inflammation and scarring. ***However, giving the baby HBIG (hepatitis B immune globulin) and the first hepatitis B vaccine 12 hours after birth will reduce the chronic infection rate to about 10%.***
- Of the 90 newborns who develop chronic hepatitis B, about 18 would eventually die from HBV-related liver disease, such as cirrhosis or liver cancer. It usually takes many years or even decades of HBV infection before liver damage becomes life-threatening.
